A KEY TO THE AMERICAN PACIFIC SHRIMPS OF THE GENUS
*Trachypenaeus* (DECAPODA, PENAEIDAE),
WITH THE DESCRIPTION OF A NEW SPECIES

ISABEL PÉREZ FARFANTE

ABSTRACT

Study of American Pacific members of the genus *Trachypenaeus* reveals that variation in armature of the telson includes not only movable spines, but also fixed spines and even no spines at all. It also confirms that the eighth somite bears two arthrobranchiae instead of one arthrobanchia and one pleurobranchia. A new species, *Trachypenaeus fuscina*, is described, the specific features of *T. faoea* Loesch and Avila are presented, and a key to the five members of the genus occurring in the region, together with their ranges, is included.

Along the Pacific coast of Latin America species of *Penaeus* are the mainstay of the shrimp fisheries; however, members of various other genera contribute to the catches in significant quantities. Among the latter, three *Trachypenaeus* have been previously recognized: *T. byrdi* Burkenroad, *T. similis pacificus* Burkenroad, and *T. faoea* Loesch and Avila. A fourth, noncommercial species, *T. brevisuturae* Burkenroad, is also found in the region. Burkenroad (1934a, 1938), presented detailed descriptions of the taxa he described, but the characters cited for *T. faoea*, except color pattern, have not proven to be diagnostic. Since the commercial *Trachypenaeus* are indiscriminately known by the common names of “tigre” and “cebra,” a definition of *T. faoea* is needed.

The study of collections of American Pacific *Trachypenaeus* has shown that yet another commercial species of this genus occurs in the area. It also pointed out a previously undescribed variation in the armature of the telson, and confirmed the identity of the gills on the eighth somite.

The measurement of total length is the linear distance from tip of rostrum to posterior end of telson, and that of carapace length is the distance from orbital margin to midposterior margin of carapace. The ratio, length of posteriormost pair of telsonic spines to width of terminal portion of telson, is presented in the following manner: length of spine/width of terminal portion = average ratio (N, number of specimens: range of variation).

GENUS *Trachypenaeus* ALCOCK

*Trachypeneus* Alcock, 1901: 15.—Burkenroad, 1934a: 49.—Burkenroad, 1934b: 73, 94.

Type-species by original designation, *Penaeus anchoralis* Bate, 1881.

The telson of the genus *Trachypenaeus* was described by Kubo (1949) as lacking fixed spines, and by Dall (1957) as possessing several pairs of lateral movable spines. Previously, Burkenroad (1934b) had proposed a grouping of the genera of the subfamily Penaeinae in four series; he defined the series *Trachypenaeus* as having a variable number of mobile lateral spines on the telson and characterized the series *Parape- naeus* as possessing one to three pairs of movable spines in addition to a fixed posterior pair, considering the presence of fixed spines on the telson as a unique character for the latter series.

In the species of *Trachypenaeus* described below, however, the posteriormost of the four pairs of spines on the telson is fixed, and in *Trachy-
penaeus byrdi Burkenroad the telson lacks spines. The telson of the members of the genus, thus, must now be more broadly characterized as having several pairs of lateral movable spines, or several pairs of movable spines anteriorly and a fixed posterior pair, or unarmed. Furthermore, the evidence presented here indicates that the character of the posteriormost pair of telsonic spines is not a unique character of the series Parapenaeus.

The branchial formula of Trachypenaeus was given by Dall (1957) as follows: pleurobranchiae on somites IX to XII; a rudimentary arthrobranchia on somite VII, anterior and posterior arthrobranchiae on VIII to XII, and a posterior arthrobranchia only on XIII; mastigobranchiae (epipodites) on VII, VIII and XII [first, second maxillipeds and third pereiopod], sometimes also on X and XI [first and second pereiopods]. All American species possess this combination of branchiae, including epipodites on the first and second pereiopods, and, in addition, a vestigial anterior arthrobranchia on somite XIII.

In Trachypenaeus, the anterior arthrobranchia on somite VIII is considerably displaced dorsally, and appears to occupy the position of a pleurobranchia; however, its attachment is on the arthrodial membrane. In Figure 1 the openings of the branchiae on somites VIII and IX, together with the proximal parts of the second and third maxillipeds, are depicted; this figure clearly shows that the two arthrobranchiae on somite VIII are attached to the arthrodial membrane, like those on somite IX, whereas the pleurobranchia on the latter somite has its origin on the pleural membrane.

Burkenroad (1934a; see also 1934b) divided the genus Trachypenaeus into two subgenera, Trachypenaeus and Trachysalambria, the latter possessing epipodites on the first and second pereiopods, and a thelycum with a median pocket on sternite XIV; the former lacks these characters. Later, Burkenroad (1959) observed that some members of Trachysalambria lack such epipodites and, thus, questioned the “usefulness” of his division. Recently, a number of species from the Indo-Pacific have been described which bear epipodites on the first two pairs of pereiopods but the thelyca, as indicated by Racek and Dall (1965), differ from that Burkenroad attributed to the members of Trachysalambria. Consequently, more investigations are needed to interpret the interrelationships of the species of the genus. It should be pointed out, however, that all American species of Trachypenaeus exhibit the characters given by Burkenroad for Trachysalambria.

The spelling of the generic name used here, Trachypenaeus instead of Trachypeneus as was originally published, is based on the decision reached by the International Commission on Zoological Nomenclature, Opinion 864, 1969, Bull. Zool. Nomencl. Vol. 25, Parts 4-5, p. 138-147.
**Trachypenaeus fuscina** SPECIES NOVA

FIGURES 1, 2, 3A, 4A-F, 5A, 6
"PINTO," "CEBRA," "TIGRE,

**MATERIAL**

Holotype.—♀, USNM 135403, off Cocodrilo, Chiapas, México, 22 m, October 31, 1969, H. Romero and G. Gómez, 35.25 mm carapace length, 135 mm total length, ratio length of spine/width of terminal portion of telson = 0.55.

Allotype.—♂, USNM 135404, off La Tapada, Chiapas, México, 22 m, July 31, 1970, D. Palacios, 26 mm carapace length, 108 mm total length, ratio length of spine/width of terminal portion of telson = 0.80.

**DESCRIPTION**

Carapace pubescent (Figure 2); dorsum densely covered by setae; paired bands of longer setae flanking posterostral carina, from rostrum to various levels in posterior third of carapace; another band on dorsal side of antennal carina; longer setae also along cervical, hepatic and branchiocardiaceal sulci, and others forming patches on orbital region and posteroventral portion of terminal portion of telson.
of antennal carina; branchial region covered with short setae; pair of small, bare, crescent-shaped to semicircular areas at anterior end of posterior third of carapace, flanking postrostral carina. Abdomen naked, except for elongate patches of long setae on each side of mid-dorsal carina on third to sixth somites, and two additional paired patches often present on sixth somite, one dorsal and other ventral to cicatrices. Telson (Figure 3A) with two pairs of longitudinal bands of long setae, one along walls of median sulcus, and other along lateral sulci.

Rostral teeth 6-7, first tooth situated immediately behind orbital margin; epigastric tooth at posterior end of anterior fourth of carapace. Rostrum reaching as far as proximal fourth of dorsal flagellum; basal portion ascending well above level of carapace, and apical one-third, unarmed portion, decreasing progressively in height, and curving upward. Adrostral carina slightly sigmoidal, ending about midway between first rostral and epigastric tooth. Postrostral carina strong, long, reaching almost to posterior margin of carapace, higher anteriorly, bearing elongate fossette, immediately behind midlength, and several pits posteriorly. Orbital angle produced into rather broad orbital spine. Gastroorbital carina and orbito-antennal sulcus absent. Postocular sulcus deep, extending posteroventrally to about level of orbital angle. Longitudinal suture well marked, long, extending along two-thirds of carapace or slightly more. Transverse suture short, clearly distinct, situated at level of coxa of third pereiopod. Antennal and hepatic spines long and strongly acuminate. Antennal carina prominent, extending to below hepatic spine. Cervical sulcus shallow and short, not intercepting longitudinal suture. Hepatic carina and hepatic sulcus well marked, and inclined anteroventrally, their length about one-third that of carapace. Postcervical line sinuous, extending from postrostral carina to near posterior end of hepatic carina. Branchiocardiac sulcus feeble, marked ventrally by obtuse carina. Pleurogastomian angle obtuse, its ventral margin sloping posteroventrally before turning backwards.

Antennular flagella subequal, shorter than either antennular peduncle or carapace, slightly longer in males than in females of same length, and proportionally longest in subadult; ratio of flagellar length to carapace length about 0.66 in shrimp of 15 mm carapace length, ratio decreasing with increasing length of shrimp to about 0.40 in shrimp with carapace length of 40 mm. First segment of antennular peduncle with disto-medial border produced into heavy, scalelike projection densely covered with long setae; distolateral spine prominent, slender and sharp; prosartema long, extending to distal end of segment; stylocerite attaining midlength of segment.

Antennal flagellum long, almost twice total length of shrimp; scaphocerite reaching distal end of antennular peduncle, elongate, its length 2½ times maximum width; lateral, thickened margin ending anteriorly in strongly pointed spine.

Third maxilliped surpassing carpopodite by as much as dactyl and one-fourth of propodus; first pereiopod reaching, at most, base of carpopodite; second pereiopod surpassing distal end of carpopodite by as much as three-quarters of dactyl; third pereiopod exceeding carpopodite by as much as propodus and one-tenth of carpus; fourth pereiopod extending to about same level as first; fifth pereiopod very long and slender, exceeding carpopodite by entire length of dactyl, and surpassing fourth by propodus and four-fifths length of carpus. Spine on basis of third maxilliped, and, as in all members of genus, on first and second pereiopods. Epipodites on first and second pereiopods deeply bifurcate, epipodites on second maxilliped and third pereiopod unifurcate; vestigial anterior arthrobranchia on somite XIII.

Abdomen with middorsal carina extending from posterior half of second to sixth somite, carina low and rounded on second, rather acute on third, and forming high and sharp keel from fourth to sixth somites; fourth and fifth somites with posteromedian V-shaped notch; sixth somite bearing middorsal spine posteriorly, small spine at posteroventral angles, and two cicatrices on each side, anterior one sensibly longer. Telson (Figure 3A) shorter than inner ramus of uropod, with median sulcus deep anteriorly and well marked posteriorly to base of terminal portion; paired rounded carinae flanking median sulcus, and sharp carinae bordering oblique, lateral
Figure 3.—Telsons. A. *Trachypenea fuscina* sp. n., ♀ 33 mm carapace length, off Cocosrilo, Chiapas, México. B. *Trachypenea faoea* Loesch and Avila, ♀ 37 mm carapace length, Ensenada de Garachiné, Golfo de Panamá, Panamá.

sulci; terminal portion (from mesial base of posteriormost spine to apex) from relatively short to long, its length relative to its width at base ranging from 1.60 to 3.70; telson armed with four pairs of lateral spines, posteriormost pair fixed and long, ratio length of spine/width of terminal portion = 0.70 (N 21: 1-0.50); other spines movable and strong, posterior pair (located at lateral base of longer fixed spines) relatively long, anterior two pairs (located posterior to midshoulder of telson) small, but usually visible with naked eye.

Petasma (Figure 4A, B) with large, hornlike, distolateral projections, broad at base, curving laterally, and opening dorsally near anterior margin by long, transverse slit; posteroventral wall of horns reflexed dorsally and produced forward into membranous flap; distomedian projections short, overhanging distoventral aperture of petasma. Ventrolateral lobule of petasma almost entirely cornified, including ventral wall of horns and dorsally reflexed lateral margin; proximomedian portion of lobule with rather flexible strip, tapering to base of distal two-fifths of median margin, there ending where corneous sclerite, curving mesially, reaches margin; soft elliptical area immediately distal to corneous section of margin. Dorsolateral lobule bearing narrow rib along proximomesial third, rib broadening proximally and turning mesially at proximal extremity resembling golf club. Dorso-medial lobule with narrow, distally bifurcate rib at base of distomedian projection, its length about one-third that of lobule. Length of petasma—from apex of distomedian projection to proximal margin of dorsolateral lobule—almost one and one-fifth times its width at level of dorsolateral projections.

In males, posterior margin of sternite XIII (Figure 4F) bearing large, elongate, subelliptical to ovate median plate, latter with obtuse to acute tip, and numerous marginal setae; anterior half of sternite XIV with strong, subpyramidal prominence, its anterolateral, ventromedially inclined edges often forming shelflike ridges.

Appendix masculina (Figure 4C-E) thick, subcircular in outline, its length along midline subequal to maximum width, and produced into two proximolateral prominences; dorsal wall cornified, except for distal and lateral margins, these, together with ventral wall, rather soft; entire, broad, median border setiferous, setae continuing on distal margin forming narrow band. Dorsal base of endopod with corneous, roughly trapezoidal sclerite, bearing strong median rib articulating distally with appendix masculina; rib with small setiferous depression on distal portion of ventral surface. Accessory sclerite on dorsolateral margin of endopod.

Thelycum (Figure 5A) with posterior part bearing anterolateral, subtriangular, heavily sclerotized projections; anterior part of sternite XIV, with platelike base, projecting as median prominence, and produced forward into pair of lateral, elongate, tonguelike flaps, extending al-

639
most to anterior margin of median plate; bases of flaps strongly inclined dorsomedially, forming depression limited posteriorly by prominence; margins of flaps often reflexed ventrally.

Platelike portion of sternite XIV naked; its lateral margins pronouncedly curving posteromedially, forming deep emarginations with projections from posterior part; basal portions of

640
flaps setose. Median plate of sternite XIII large, oval, strongly concave ventrally, with margin tumid, and bearing setae; plate extending posteriorly joining dorsal wall of flaps, thus giving rise to median pocket; latter bearing paired apertures of internal seminal receptacles laterally (Figure 6B). In impregnated females, median pocket occupied by sclerotized, sperm-free, brownish component of spermatophores, extending almost to anterior margin of median plate. Hardened, glutinous material, extruded with spermatophores, protruding through slit between flaps, forming plug on ventral surface of flaps.

Internal seminal receptacles (Figure 6A, B) consisting of paired, longitudinally arranged, trilobed, membranous sacs: single, large, posterior lobe, dorsal to median pocket, extending caudally almost to posterior margin of sternite XIV; and two small lobes, one directed anteromesially, dorsal to median plate, and the other laterally, dorsal to small hood of sternite XIV.
Seminal receptacles derived from paired, deep invaginations at anterolateral extremities of sternite XIV. In impregnated females, seminal receptacles enclosing main component of spermatofores, consisting of thin walled sac containing subspherical masses of spermatozoa.

COLOR

Juveniles recently caught in inshore water of Oaxaca, México, light buff with brownish red suffusion; transverse, dark reddish brown bands on posterior part of abdominal somites; bands convex anteriorly, with widest portion on middorsal line, extending ventrally and forming patch on posterior half of pleuron. Preserved adults (fresh ones not observed by me) with distinct dark abdominal bands, similar to those in juveniles.

SIZE

Largest specimen examined,♀40.5 mm carapace length, about 150 mm total length, from off La Tapada, Chiapas, México, depth 7-9 m. Males smaller than females, largest observed δ allotype, 26 mm carapace length, 108 mm total length.

DISTRIBUTION

*T. fuscina* has been found in the Golfo de Tehuantepec, along the coasts of Oaxaca and Chiapas, México, and in the Golfo de Guayaquil, as far south as Tumbes, Perú. Although this species and *T. faoea* are sympatric in the Golfo de Guayaquil, apparently *T. fuscina* ranges farther north, since *T. faoea* has not been found along the southwestern coast of México.

REMARKS

*T. fuscina* is very closely related to *T. faoea*, but differs from it in several aspects—mainly in features of the telson (Figure 3A). In *T. fuscina* the posteriormost pair of spines is longer, and fixed instead of movable, this being the only member of the genus *Trachypenaeus* with immovable spines on the telson; the anterior three pairs of telsonic spines are stronger than in *T. faoea*, particularly those spines at the lateral base of the posteriormost pair; also the median sulcus is well marked as far as the base of the terminal portion of the telson. In *T. fuscina* the platelike base of the anterior part of sternite XIV in females (Figure 5A) is naked, and its lateral margins curve strongly posteromesially, giving rise to a deep emargination at the junction of the plate with the posterior part of the thelycum (sternite XIV). In males, the median plate of sternite XIII narrows anteriorly, usually tapering to a point (Figure 4F).

It should be pointed out that during copulation in this species, as well as in *T. faoea*, the male transfers to each seminal receptacle a very thin sac containing the spermatozoa, which are grouped into subspherical masses. These masses are not individually transmitted to the seminal receptacles as believed by Burkenroad (1934b), a phenomenon considered by him to be typical of the genus *Trachypenaeus*.

ETYMOLOGY

Fuscina, L., = three-pronged fork—referring to the trifid appearance of terminal portion of telson.

*Trachypenaeus faoea* LOESCH AND AVILA

MATERIAL

Neotype.—♀, USNM 135398, Playas, Ecuador, January 7, 1964, Ortiz, 28 mm carapace length, 110 mm total length, ratio length of spine/width of terminal portion of telson = 0.25.

TYPE MATERIAL

Loesch and Avila (1964) did not cite any material in particular; however, as the title of their work indicates, the specimens studied and illustrated in their keys were from Ecuador. Because of the close similarities between T. faoea and T. fuscina it seems mandatory that a neotype of T. faoea be selected, so that no confusion will arise as to the identity of the species of Loesch and Avila. Therefore, a neotype is here designated from a lot of females of Trachypenaeus faoea collected in Playas, Ecuador, which was identified and sent to me by the authors of the species. Inasmuch as the combination of specific morphological characters of this species have not been indicated previously, they are presented here.

“Trachypenaeus faoe” first appeared in the literature in the report of a survey of the shrimp fisheries of Central and South America by Lindner (1957). This author grouped it with T. byrdi as one of the “larger zebra shrimp,” noting the “blue-black” stripes on the abdomen and citing various other common names. Lindner, obviously, did not intend to describe the species, and did not include any specific character. He reported “T. faoe” in the shrimp fisheries of the American Pacific, from México to Perú, including El Salvador, Costa Rica, Panamá, Colombia, and Ecuador. Later (U. S. Fish and Wildlife Service, 1962) the species was cited as one of “medium and small” shrimp found in the catches of Guatemala.

The original description of the species appeared in the keys to the commercial penaeid shrimps of Ecuador by Loesch and Avila (1964), and was mistakenly ascribed to Burkenroad. As stated by Avila and Loesch (1965), Burkenroad had planned to describe the species, but had not done so prior to the publication of their keys, nor has his description appeared since. T. faoea was distinguished from other penaeids found in the Ecuadorian catches on the basis of four morphological characteristics and color pattern. The following characters were cited: “No teeth on ventral portion of rostrum. . . . No well-developed dorsolateral sulcus on the posterior part of the last abdominal segment. . . . Backward-pointing dorsal spine on last abdominal segment only. . . . Telson not armed with lateral armature.” The first two characters are shared by many species treated in their keys, and are actually supraspecific; the third character is common to all but one (T. byrdi Burkenroad) of the American Pacific Trachypenaeus, and the fourth is inaccurate: T. faoea does possess small lateral spines on the telson.

The color of the species was described as follows: “Tail section light anteriorly and dark posteriorly on each abdominal segment . . . . No distinctive patterns on second and third abdominal segments, each segment similarly colored with wide dark band covering ⅔ the width of posterior part of each abdominal segment. More than ⅔ of color of tail is dark (dark brown).” An entire animal and a separate abdomen were figured. In both illustrations the telson appears unarmed. The figure of the entire animal is accompanied by the rostral tooth formula, 6-7. Of the characters cited, color is the only one that appears to be typical of the species, and it can only be applied to identification of fresh or recently preserved animals. It is unfortunate that circumstances prevented Loesch and Avila, who dealt with large numbers of specimens, from publishing a detailed description of T. faoea.

T. faoea is very closely related to T. fuscina, and except for the following, the above descrip-
tion of *T. fuscina* also applies to *T. faoea*: the armature of the telson, the shape and pubescence of the platelike base of the anterior part of sternite XIV in females, the marginal contour of the median plate of sternite XIII in males, and perhaps color.

In *T. faoea* the posteriormost of the four pairs of spines on the telson (Figure 3B) are movable instead of fixed, and shorter than those of *T. fuscina*, the ratio length of spine/width of terminal portion = 0.40 (N 47: 0.75-0.20); the other three pairs of movable spines, including those located at the lateral base of the posteriormost spines, are minute, actually microscopic. In *T. faoea* the median sulcus of the telson is deep anteriorly but hardly perceptible or indistinct posteriorly.

In males of *T. faoea* the median plate at the posterior margin of sternite XIII (Figure 4G) usually varies from subtrapezoidal (widest anteriorly) to suborbicular. In females, the structure of the thelycum (Figure 5B) is similar to that of *T. fuscina*; however, lateral margins of the platelike base of the anterior part of sternite XIV are almost straight, not or barely curving posteromesially, forming about 90° angles with projections of the posterior part; furthermore, the lateral areas of that platelike portion are studded with rather densely set setae, the latter extending onto basal portions of the flaps.

Avila and Loesch (1965) described the color of recently preserved juvenile specimens of *T. faoea* as dark blue or purple with light uropods. They noticed that specimens preserved for 2 days in 5% Formalin exhibit a clear, horse-shoe shaped band on the first three abdominal somites, which is open anteriorly. These observations were based on material from Ecuador and differ from those made by me on *T. fuscina*. Recorded notes on color are so limited that conclusions in regard to differences in this character between the two species must await further observations throughout their ranges.

**DISTRIBUTION**

Although this species has been reported from as far north as the coasts of Guatemala, El Salvador and Costa Rica, the collections available to me are limited to the area from Panamá to Ecuador. Examination of additional samples of
"cabra," or “tigre” shrimp from Central and South America will be necessary to establish the actual distribution of *T. faoea* as well as that of *T. fuscina*, both known by the same common names.

With the discovery of an additional species of *Trachypeneaeus* in the American Pacific, it seems appropriate to present a key to the five members of the genus occurring in the region, together with the range of each.

**KEY TO THE AMERICAN PACIFIC SPECIES OF *Trachypeneaeus***

1. Carapace with longitudinal suture short, not extending to hepatic spine. Third maxilliped lacking spine on basis; first pereiopod bearing spine on ischium. Thelycum with median plate armed with small anteromedian spine (clearly distinct in juvenile, barely perceptible in adult); anterior part of sternite XIV shorter than posterior part, and not produced as paired flaps (Figure 7A). Petasma with dorsal spinelike projection near apex of horn .

   **T. brevisuturae** Burkenroad

   (From off Punta Arenas, Golfo de California, to El Salvador).

2. Spine present on posterior end of middorsal carina of last two, three, or four abdominal somites. Telson unarmed. Thelycum with slit between flaps never reaching posterior part of sternite XIV, and with median plate short, not reaching gonopores (Figure 7B) .

   **T. byrdi** Burkenroad

   (From Guatemala to Golfo de Guayaquil)

3. Rostral teeth 7 to 10, usually 8 or more. Telson with proximal triangular patch of long setae on each side of median sulcus. Thelycum with median plate not excavated, short, and protruding ventrally on midportion. Anterior part of sternite XIV lacking platelike base and bearing subrectangular flaps, extending only to posterior part of median plate (Figure 7C) .

   **T. similis pacificus** Burkenroad

   (From Bahía Concepción, Golfo de California, to Tumbes, Perú)

4. Telson with posteriormost pair of lateral spines fixed. Thelycum with platelike base of anterior part of sternite XIV lacking setae on each side, its lateral margins strongly curving posteromesially, forming deep emargination with posterolateral projections (Figure 5A) .

   **T. fuscina** sp. n.

   (Golfo de Tehuantepec and Golfo de Guayaquil)

5. Telson with posteriormost pair of lateral spines movable. Thelycum with platelike base of anterior part of sternite XIV setose, its lateral margins almost straight, forming about 90° angles with posterolateral projections (Figure 5B) .

   **T. faoea** Loesch and Avila

   (From Guatemala to Golfo de Guayaquil)
ACKNOWLEDGMENTS

In addition to the collections in the United States National Museum (USNM), Smithsonian Institution, material was obtained from the Instituto de Biología, Universidad Nacional Autónoma de México (IBUNM), through Alejandro Villalobos F. and Jorge A. Cabrera, and the Instituto Nacional de Investigaciones Biológico-Pesqueras, Secretaría de Industria y Comercio de México (INIBP), through Amin Zarur and Héctor Romero. I wish to thank the above mentioned persons for their assistance and cooperation. The two collections from Mexico have been divided, one part deposited in the corresponding Mexican institution and the other at the USNM. I am indebted to Quinto Avila and Harold Loesch for critical material from Ecuador, and to Leslie W. Knapp for making available to me specimens from Colombia. Horton H. Hobbs, Jr., Fenner A. Chace, Jr., and Bruce B. Collette offered critical comments that considerably improved the manuscript. The illustrations are by the artist María M. Dieguez, National Marine Fisheries Service Systematics Laboratory.
