SYSTEMATICS AND TAXONOMIC REMARKS ON 
PINNOTHERES MULINIARUM RATHBUN, 1918
(CRUSTACEA: BRACHYURA: PINNOTHERIDAE)

Ernesto Campos

Abstract.—The new genus Juxtafabia is proposed to receive the clam crab Pinnothetes muliniarum Rathbun, 1918. The primary diagnostic features are: third maxilliped with carpus and propodus stout, subequal in length; propodus suboblong, with distal end obliquely rounded and a lunate and broad dactylus inserted near its proximal end; and male abdomen widest at somite 3, narrowing at somite 4 which is fused to somite 5, and telson longer than broad. The type species, Pinnothetes muliniarum Rathbun, 1918, described from a pre-hard stage male is considered to be a senior synonym of P. reticulatus Rathbun, 1918, which was described on the basis of an adult female. Description and figures of the young pre-hard stage, adult hard stage male, adult female, complete synonymy, known distribution, and host are presented.

Resumen.—El nuevo género Juxtafabia se propone para recibir al cangrejo almejero Pinnothetes muliniarum Rathbun, 1918. Sus características diagnósticas primarias son: tercer maxilipedio con el carpus y propodus iguales en longitud y robustos; el propodus suboblongo tiene su final distal oblicuamente redondeado y lleva proximalmente al amplio y lunado dactilus; y el abdomen, en el macho, se ensancha en el somita 3, se adelgaza en el 4 el cual está fusionado al 5, y con un telson más largo que ancho. La especie tipo, Pinnothetes muliniarum Rathbun, 1918, que fue descrita en base a un macho en fase pre-dura es aquí considerado como un sinónimo antiguo de P. reticulatus Rathbun, 1918, la cual fue descrita sobre la base de una hembra adulta. Descripción y figuras de las fases masculinas pre-dura y dura, la hembra adulta, la sinonimia completa, la distribución conocida y los huéspedes para esta especie, se registran.

The Pinnothidae is a group of symbiotic and sexually dimorphic crabs that undergo a series of morphological changes during their postplanktonic development. This has resulted in some mistaken identifications representing developmental stages of the same species. For example, Williams (1965) found that Pinnothetes depressus Rathbun, 1918 was the pre-hard stage male of P. os- treum Say, 1817, and Campos (1989b) concluded that P. pubescens (Holmes, 1894) is a young female of Tumidotheres margarita (Smith, 1869). Recently, Green (1985) determined that P. jamesi Rathbun, 1923, described from a hard stage male (sensu Christensen & McDermott 1958) is a junior synonym of P. reticulatus Rathbun, 1918, a species which was described on the basis of a post-hard stage female. Postplanktonic stages of P. reticulatus collected in the upper Gulf of California in 1986–1987 confirmed Green’s conclusions, and a comparison of the pre-hard stage male with the holotype of P. muliniarum Rathbun, 1918 revealed no difference. In addition, a morphological analysis of these specimens has led to the
proposition of a new genus for this species. This new genus most closely resembles *Fabia* Dana, 1851.

Specimens for this study were obtained from: National Museum of Natural History, Smithsonian Institution, Washington, D.C. (USNM); Colección Carcinológica, Instituto de Biología, Universidad Nacional Autónoma de México (EM) and Facultad de Ciencias, Universidad Autónoma de Baja California (UABC). The abbreviation cw refers to carapace width.

Systematics and Taxonomic Account

**Juxtafabia**, new genus

**Diagnosis.**—Female carapace subglobular, dorsal regions weakly defined. Third maxillipede with ischium and merus indistinguishably fused, ventral margin angular, dorsal margin gently convex; palp slightly shorter than ischium-merus, carpus and propodus subequal in length, stout, latter article suboblong with distal end obliquely rounded, dactylus lunate, broad, ventrally inserted near proximal end of propodus. Abdomen with 7 free somites, laterally reaching to coxae of walking legs, distally covering buccal cavity.

Male carapace subglobular, regions weakly defined, pterygostomian region elevated, eyes visible in dorsal view; third maxilliped similar to that of female; abdomen widest at somite 3, narrowing at somite 4 which is fused to somite 5, telson longer than broad.

**Type species.**—By present designation and monotypy, *Pinnotheres muliniarum* Rathbun, 1918. Gender feminine.

**Distribution.**—Upper Gulf of California, México to Costa Rica, Central America.

**Hosts.**—Mollusca, Bivalvia: species of *Chione, Polymesoda, Protothaca* and *Tagelus.*

**Etymology.**—The generic name is derived from the latin *Juxta*, close to, at side of, and the generic name *Fabia*. The name has been selected to emphasize the resemblance of *Juxtafabia* and *Fabia.*

**Remarks.**—Other genera in the Pinnotheridae which also have the ischium and merus of the third maxilliped indistinguishably fused differ from *Juxtafabia* as follows: *Dissodactylus* Smith, 1870, *Clypeasterophilus* Campos & Griffith, 1990, *Parapinnixa* Holmes, 1894 and *Sakaina* Serène, 1964 have an exopod without flagellum (Fig. 1A); *Calyptraeotheres* Campos, 1990, *Ostracotheres* H. Milne-Edwards, 1853 and *Xanthasia* White, 1846 have a palp with two articles (Fig. 1B); *Limotheres* Holthuis, 1975 and *Orthotheres* Sakai, 1969 have the dactylus inserted distally on the propodus (Fig. 1C); *Pinnixa* White, 1846 and *Scleroplax* Rathbun, 1893 have a lobe on the external margin of the exopod (Fig. 1D); *Fabia* Dana, 1851, *Tumidotheres* Campos, 1989b, and *Durckheimia* De Man, 1889, have a small palp with the dactylus inserted on the middle of the propodus (Fig. 1E); and *Pinnotheres* Bosc, 1802 s. str. has a linear and slender dactylus inserted proximally on the inner margin of the spatulate propodus (Fig. 1F), and seven free abdominal somites. Additional differences between *Juxtafabia* and the above genera can be found in Bürger (1895), Rathbun (1918), Tesch (1918), Serène (1964, 1967), Holthuis (1975), Campos (1989a, 1989b, 1990) and Campos & Griffith (1990).

The new genus *Juxtafabia* most closely resembles the genus *Fabia*. Males in both genera have two or more abdominal somites fused. However, there are no morphological similarities between females of the two genera. Larvae of *J. muliniarum* resemble zoeae of *Fabia* and *Pinnixa*. Zoeae in these genera have a common pattern of setae on their appendages, a carapace with moderately developed rostral, lateral and dorsal spines and a distinctive abdominal shape. These genera share a very distinct lateral and posterior expansion on the fifth abdominal somite (Fig. 2A–E). The genus *Pinnixa*, however, has an elongated telson which is quite distinct from that in *Juxtafabia* and *Fabia*. Whether these morphological similarities
Fig. 2. Dorsal view of zoeal abdomen. A, Juxtafabia muliniarum (Rathbun, 1918); B, Fabia subquadrata Dana, 1851; C, Fabia sp.; D, Pinnixa longipes (Lockington, 1877); E, Pinnixa aff. rathbuni Sakai, 1934 [D and E redrawn from Bousquette (1980:596, fig. 4A) and Konichi (1983:282, fig. 14C) respectively].
between males and larvae have phylogenetic implications remains to be determined.

**Juxtafalia muliniarum** (Rathbun, 1918), new combination

**Type locality.**—Lower California (Baja California, Mexico).

**Distribution.**—Gulf of Santa Clara (Gulf of California), Baja California, Mexico to Costa Rica.

**Hosts.**—Mollusca, Bivalvia: *Chione californiensis* (Broderip), *C. fructifaga* (Sowerby), *C. tumens* (Verrill), *Polymesoda inflata* (Philippi), *Protothaca grata* (Say) and *Tagelus affinis* (C. B. Adams).

**Material examined.**—Holotype of *Pinnotheres muliniarum*, Lower California, male, cw 3.6 mm (fide Rathbun 1918), USNM 23443.—Holotype of *P. reticulatus*, off San Jose Island, Baja California Sur, 25°02'15"N, 110°43'30"W, 17 fms (31 m), S.Sh., 17 Mar 1889, Station 3002 Albatross, female, cw 9.2 mm (fide Rathbun 1918), USNM 18217.—1 female, cw 2.9 mm, Gulf of Santa Clara, Baja California, 25 Apr 1990, in *Chione fructifaga*, UABC.—12 ovigerous females, cw 5 to 10 mm, 4 young males, cw 1 to 2.2 mm, Campo El Pescador, on coast 4.5 km North of San Felipe, Baja California, 1988, in *Protothaca grata, Chione californiensis* and *C. fructifaga*, UABC.—7 young males, cw 1 to 2.3 mm, 11 adult males, cw 2.2 to 3.4 mm, and 30 females, cw 4 to 10 mm, Laguna Pecebú, about 23 km south of San Felipe, 1987–88, in *P. grata* and *Tagelus affinis*, UABC.—1 female, cw 5.7 mm, Puertecitos, km 72 road San Felipe-San Luis Gonzáaga, Aug 1986, in *P. grata*, UABC.—1 ovigerous female, cw 10 mm, San Marcos Island, north of La Yesera (27°17'N, 112°07'W), 16 May 1987, in *Chione tumens*, EM.

**Male pre-hard stage.**—Carapace transversely subglobular, soft, posterior margin convex; front slightly projected and strongly deflexed (Fig. 3). Third maxilliped with palp slightly shorter than ischium-merus (Fig. 5A); carpus subequal to propodus in length, latter suboblong, with distal end obliquely rounded; dactylus broad, lunate, ventrally inserted near proximal end of propodus, nearly reaching to distal end of last article.

Chelipeds stouter than walking legs, merus widening slightly distally, dorsal margin convex, ventral margin straight; fingers subequal, slightly deflexed, curved at tip where they cross; cutting edge of dactylus with small tooth.

Relative length of the walking legs 2 > 3 > 1 > 4, fourth leg not overreaching carpus of third leg; margin of legs hairy, specially on meri; dorsal margin of propodi convex, ventral margin in legs 1–3 straight, concave in leg 4; dactyli 1–3 hook-like; dactylus 4 less curved than on legs 1–3.

Abdomen widest at somite 3, narrowing at somite 4, telson longer than broad, distally rounded. Somites 4 and 5 fused.

Gonopods simple, curved at base, distally straight (Fig. 5B).

**Male hard stage.**—Carapace (Fig. 4) transversely subglobular, well calcified, lateral margins with a heavy fringe of hair-like setae; pterygostomian region higher than in pre-hard stage so that eyes are more conspicuous in dorsal view; frontal region occasionally produced; posterior margin almost straight. Third maxilliped similar to that of male pre-hard stage (Fig. 5C).

Chelipeds no more stout than walking legs;
manus widening distally; dorsal margin convex; fingers subequal, curved and crossed at tip; ventral margin almost straight; pollex with 2 acute teeth on proximal half of cutting edge, between them a notch where truncate tooth of dactylus fits.

Walking legs stout, dorsal and ventral margin of meri fringed with setae; propodi tapering distally, dorsally convex, almost straight ventrally; dactyli equal to those of pre-hard stage. External face of carpus and propodus of walking legs 2 and 3 with long swimming setae.

Abdomen similar to that of pre-hard stage, but somite 7 occasionally subrectangular (Fig. 5D).

Fig. 3. *Juxtafabia muliniarum* (Rathbun, 1918); dorsal view of pre-hard stage male. Carapace length = 2.3 mm.

Fig. 4. *Juxtafabia muliniarum* (Rathbun, 1918); dorsal view of hard stage male. Carapace length = 3.14 mm. Single setae shown on dorsal and ventral margin of the last walking legs may actually be plumose setae.
Gonopods similar to those in pre-hard stage, but longer and slender (Fig. 5E).

Female (ovigerous).—Carapace (Fig. 6) subglobular, broader than long, soft, slightly convex; gastric region elevated on medial line and separated by broad depression from branchial region; a lunate depression near hepatic margin. Front slightly convex in dorsal view, scarcely projecting beyond curve of anterolateral margin. Eyes globular, completely filling orbits, visible dorsally, cornea evident. Epistome and labium similar in length and width. Antenna with blocky basal articles, flagellum minute, not overreaching upper margin of orbit. Antennulae placed in wide fossettes not larger than orbits.

First 2 articles of palp of third maxilliped broad, subequal in length; dactylus curved, lunate, attached proximally and reaching to end of suboblong propodus (Fig. 5F).

Chelipeds and legs short, pubescent; chelipeds hairy on inner faces; manus subelliptical, increasing slightly distally, lower mar-
gin straight, upper slightly convex; pubescence arranged in reticulate pattern, the interstices of which are smooth and of darker color (in alcohol); fingers moderately stout, tips hooked toward each other, prehensile edges of each armed with 2 teeth of which that near base of dactylus is largest, other minute teeth between them.

Walking legs furnished with long setae on lower margin, specially on propodus of first and fourth leg; relative length of legs $2 > 3 > 4 > 1$, the second leg may be asymmetrical, with propodus and dactylus of left leg longer than on right one; ventral margin of propodus of second and third leg concave; ventral margin of propodus of first and fourth leg straight; dactyli 1, 2 and 3 similar, curved and with slender tips, first shortest, second longest; dactylus 4 much longer than those preceding and may be longer than its propodus.

Abdomen with 7 free somites, longer and broader than carapace (modified from Rathbun 1918).

Remarks.—The study of males in hard stage (host, *Tagelus affinis*) and females in post-hard stage (host, *Protothaca grata* and *T. affinis*) collected during the spring and summer of 1986–1987 at Laguna Percebú, south of San Felipe, led to the confirmation of Green's (1985) conclusion that *Pinnothrix jamesi* is a junior synonym of *P. reticulatus*. Subsequent collecting of pre-hard stage males (host, *Chione Californiensis*) of a pinnotherid crab from Campo El Pescador showed no difference with Rathbun's (1918)
holotype of *Juxtafabia muliniarum*. Examination of additional males collected from *T. affinis* showed that some specimens represented pre-hard stage males which were identical to those previously identified as *J. muliniarum* (from El Pescador). The other specimens were hard stage males identical to *P. jamesi*. To determine whether both types of males examined were conspecific, specimens of pre-hard stage males (*J. muliniarum*) were kept alive until they molted to a hard stage identical to those identified as *P. jamesi*. These results and the study of the complete postplanktonic female stages from San Felipe and vicinity, led to the conclusion that *J. muliniarum, P. jamesi* and *P. reticulatus* represent the same species. *Juxtafabia muliniarum* was the first named species and, therefore, is the senior synonym of the other two taxa.

**Acknowledgments**

Many thanks to Prof. A. Carvacho for allowing me to revise the holotypes of *J. muliniarum* and *P. reticulatus* which were kindly loaned to him by Dr. R. B. Manning (Smithsonian Institution). I also thank Prof. Carvacho and J. F. Bergerault for loaning additional specimens of *J. muliniarum*. My deep gratitude goes to my wife Alma Rosa for hard field and laboratory work, for preparing original figures, and for commenting on early manuscript versions and most importantly for continued encouragement to see this paper to completion. This work was partially supported by the program “Sistématica de Crustáceos” of the Facultad de Ciencias, Universidad Autónoma de Baja California and by agreements SEP-UABC 087-01-0426 and 089-01-0352 and CONACyT 0482-N9108.
